

Programmable Plants — A technology platform for sustainable abundance

Opportunity space

v1.0

Angie Burnett, Programme Director

CONTEXT

This document describes an early opportunity space from which we believe one or more funding programmes can emerge. We've sketched out some of our early thinking to spark your interest, and invite you to imagine relevant potential programmes with us, or suggest new directions.

We'll publish updated versions of this document as our thinking evolves. Sign up [here](#) to receive those updates and learn about any funding opportunities that emerge from this opportunity space.

An ARIA opportunity space should be

- + important if true (i.e. could lead to a significant new capability for society),
- + under-explored relative to its potential impact, and
- + ripe for new talent, perspectives, or resources to change what's possible.

SUMMARY

Plants have paved the way for human existence and hold tremendous potential to solve some of our most pressing challenges such as food insecurity, climate change and environmental degradation. Programmable plants can secure our future on earth — providing not just food, but a sustainable and thriving biosphere for future generations.

BELIEFS

The core beliefs that underpin/bound this area of opportunity.

1. Today's agricultural system is struggling to address the coupled challenges of sustainable food supply and stable climate → **we need a paradigm shift to accelerate agricultural innovation.**
2. Plants represent 80% of earth's biomass and are rapidly, cost-effectively and widely distributed across our planet → **plants represent an ideal technological platform to provide low-cost, sustainable resources at scale.**
3. Advances in gene editing and genetic modification are revolutionising our ability to tailor the traits of organisms → **we can predictably and efficiently develop amazing new plants to provide all of society with abundant and sustainable resources: food, fuel, medicine, shelter and beyond.**

OBSERVATIONS

Some signposts as to why we see this area as important, under-explored, and ripe.

Climate change, especially the uncertainty and severity of extreme weather events, is stressing the global agrifood system. Plant engineering can both mitigate the stress and help address the root cause.

It typically takes eight years to develop a new crop variety in the UK. During the COVID-19 pandemic, we made a vaccine in one year instead of ten.

How can we similarly fast-track crop development to stay abreast of our changing climate?

Crop optimisation has historically been limited by trade-offs between yield and resilience. We know of mechanisms to regulate these trade-offs (e.g. hormonal intervention by fungal endophytes), but how can we overcome them?

Gene editing using CRISPR is faster and more precise than genetic modification, and increases the predictability of phenotypes ten-fold.

Transformation - the incorporation of new genes into plants - enables us to add and change plant functions. Tissue culture is a major bottleneck that limits transformation speed and transferability between species. The regeneration phase for plant material in tissue culture can take months.

In the future we'll design, write and build fully synthetic crop genomes.

Moving out of tissue culture would be huge!

Revolutionising transformation would unlock the power of gene editing, providing major benefits to breeding and research. We need a method that is high-yielding, transferable between species and does not rely on tissue culture.

De novo pathways and fully synthetic de novo organism synthesis including a minimal genome have been proven in bacteria.

Possibilities for a programmable plant

TECHNIQUES

TRAITS + APPLICATIONS

Gene editing to improve nutrient composition.

Stable yield of a highly nutritious easy to process, food product.

Insertion of novel mini chromosome or plasmid for synthesis of novel compounds.

Leaves contain dosage controlled pharmaceuticals e.g. edible vaccines for livestock.

Engineered microbes living in symbiosis deliver rapid, tunable benefits and reduce need for agricultural inputs.

Segmented stem facilitates hydraulic isolation to allow repeated harvesting for food and biofuels.

Roots sequester carbon and interface with novel beneficial microorganisms.

Emergent possibilities include meristems and pollen targets. Directly editing seeds could be on the horizon!

A transferable transformation method would enable greater use of orphan crops and crop wild relatives to increase diversity and resilience.

In the short term, we could develop synthetic plant chromosomes and chloroplasts *in vivo* that will transfer gene modules into crops to deliver specific functionalities.

For transient in-field adaptations, viral delivery of genetic material can transform crops.

Can we develop a universal transient gene expression method?

AI can guide edits and select transformed plants but we need innovations in method development to streamline design.

Target and network discovery are needed to make synthetic chromosomes and chloroplasts effective in multiple species. Breakthroughs are needed for centromere formation for bottom-up synthetic chromosomes, since centromere formation in plant cells is under epigenetic control.

ENGAGE

We invite you to shape our efforts by providing feedback and surfacing breakthrough ideas related to this opportunity space. Our next step will be to formulate a programme that directs funding across research disciplines or institutions toward a focused objective. We also plan to open up seed funding for researchers whose bold aspirations are unlikely to be funded elsewhere.

Sign up for updates and share your feedback [**here**](#) – we will read anything you send.
